

# Course Structure

1. Software Quality Assurance
2. Testing Fundamentals
3. Code-based Techniques
4. Specification-based Techniques-Part I
5. Inspection Technique
6. Test Tools
7. Measuring Software Quality
8. TDD

# Spec.-based Testing

# Learning Objectives

- understand the characteristics of specification-based testing, its advantages and disadvantages;
- select test cases using specification-based techniques:
  - input domain testing
  - Orthogonal array testing
  - equivalence partitioning testing
  - boundary value testing
  - classification tree
  - worst case testing
  - special value testing
  - output range
  - state machine testing
  - decision table testing
  - cause effect graphing
  - scenario testing
  - statistical testing
  - risk-based testing

# Example Black Box

For a soda vending machine, to buy a can of Coke, we insert money into the machine and get our soda.

From testing perspective:

- The coins that we insert into the machine are **INPUT**.
- The soda is an **OUTPUT**.
- The buttons to select type of soda and the slot where we insert our coins are the **USER INTERFACE (UI)**.
- The internals of the vending machine is like a **black box**, because we have no idea about the concrete mechanism that exchanges coins for soda.

**OUTPUT**

# What is Spec-based Testing?

## ► Introduction

Spec-independent

Spec-dependent

Other

Also called **Black-box testing**, or **functional testing**.

- done without any knowledge of the program
- attempts to derive sets of inputs that will fully exercise all the **functional requirements** of a system.

**Identify test cases from the specification.**

# Spec-based Testing

## ► Introduction

Spec-independent

Spec-dependent

Other

**Black-box testing** can be applied at unit test, integration test, and system test level.

At unit testing, each unit provide some services (or functions, such as sorting a list of numbers). We can apply black-box testing without looking at the source code.

At system testing, we look at higher level functions of the whole system. Again, no looking at source code.

Attempts to find these errors:

- 1 incorrect or missing functions,
- 2 interface errors,
- 3 errors in data structures, external database access,
- 4 initialization and termination errors.

# Specification-based Testing

## ► Introduction

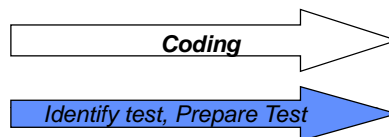

Spec-independent

Spec-dependent

Other

### Advantages:

- ☺ Independent of the implementation. If implementation changes, no need to change the test cases.
- ☺ Identify faults missed by code-based testing.
- ☺ Test case development can occur in **parallel** with code development.

### Disadvantages:

- ⊗ Difficulties in deriving tests:
  - Spec. expressed in an untestable fashion
  - Spec. has no structure and no sense of ordering
  - Spec. may be ambiguous and imprecise due to the use of natural language
- ⊗ Parts of the code may not be fully exercised by black-box tests, e.g., a true/false condition in the specification may be implemented with many LOC.
- ⊗ Cannot test "hidden" function implemented in the code, but not specified in the spec..

# A Common Situation

## ► Introduction

Spec-independent

Spec-dependent

Other

At UAT

*Developer: "Here is the system built according to your specification."*

*User: "This isn't the software we need!"*

**Requirement defects are the most disastrous and costly!**

# High Quality Spec. is Critical

## ► Introduction

Spec-independent

Spec-dependent

Other

- The most costly errors are those made early in the development cycle
- Misunderstandings about the requirements specification lead to early mistakes
- Programmers need the specification to tell what is needed
- Also, maintenance actions must be based on requirements specification.

*"Better specification enable better testing, and better testing requires better specifications"*

Anonymous

# Common Problems with Spec.

## ► Introduction

Spec-independent

Spec-dependent

Other

### ⌘ Missing description (**incomplete**)

Does not cover ALL

Feature set, Use cases, Usage scenarios

### ⌘ Contradictory description (**inconsistent**)

### ⌘ Confusing (**ambiguous**) –multiple meaning

Force the developers to make assumption on their own! *Their assumption may be different from that of the client/user.*

**Big Problem**

## Some Facts about requirements:

- ⌘ Half of the features provided in most software are never used.
- ⌘ More than half of the effort on most software systems is wasted.
- ⌘ 80% of requirements errors found in system testing are a result of incorrect facts about the requirements or omitted requirements.

# An Example Specification from a real project

*"The exception information will be in the ABC file, too."*

### Programmer's interpretation:

"Another *place* the exception information appears is the ABC file."

### But, what the customer mean:

*"Another type of information that appears in the ABC file is the exception information."*

In fact, this information was not duplicated elsewhere. The customer's "too" led to the loss of valuable and unrecoverable information!

# Exercise 1

## Introduction

### ► Ambiguity

Spec-independent

Spec-dependent

Other

Identify some of the problems with the following specification:

1. For 90% of cases, the response time of on-line request should be less than 1 second and less than 4 seconds for the rest.
2. For 90% of cases, the response time of wildcard search must be within 10 seconds.
3. Write a program that inputs a sequence of integers and outputs the sorted version of this sequence.

*"We should take full responsibility for failing to meet our customer's needs.*

*For a retail store, it should take full responsibility if it fails to satisfy the customer with its product. It can't blame the customer for failing to clearly express his or her needs."*

Al Davis

# System Specifications

## Introduction

Spec-independent

Spec-dependent

Other

- ⌘ System spec. consists of functional spec. and non-functional spec.
- ⌘ Functional specifications can be formal (mathematical), or informal (in a natural language like English)
- ⌘ Functional specification usually contains at least 3 kinds of information:
  - ⌘ The intended **inputs**
  - ⌘ The corresponding intended **actions**
  - ⌘ The corresponding intended **outputs**

**Spec-based Testing mainly identify test cases for testing functional spec.**

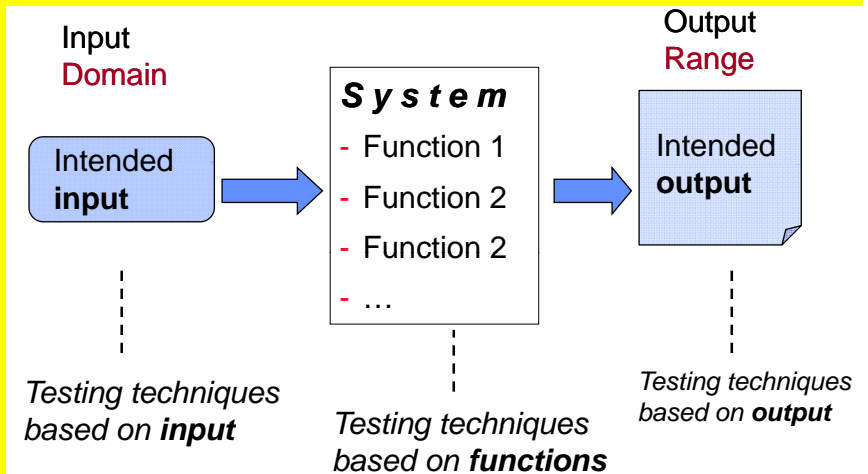

# When we Test . . .

## Introduction

Spec-independent

Spec-dependent

Other

## 3 kinds of Black-box testing methods

## Introduction

Spec-independent

Spec-dependent

Other

Based on the 3 kinds of information:

- ⌘ **Input coverage tests**, based on an analysis of the *intended inputs*, independent of their actions or outputs
- ⌘ **Output coverage tests**, based on an analysis of the *intended outputs*, independent of their inputs or actions
- ⌘ **Functionality coverage tests**, based on an analysis of the *intended actions/functions*, with or without their inputs and outputs.

## Classification of Spec-based Testing (1)

## Introduction

Spec-independent

Spec-dependent

Other

Testing techniques that are Independent of specification technique:

### Based on the input

- ✓ Input domain testing
- ✓ Equivalence partitioning (等价类划分)
- ✓ Boundary value analysis (边界值分析法)
- ✓ Worst case testing

### Based on the Function to be Computed (or Output)

- ✓ Special-value testing
- ✓ Output domain coverage

# Classification of Spec-based Testing (2)

## Introduction

Spec-independent

Spec-dependent

Other

## Testing techniques that are Dependent on the specification technique:

- Algebraic
- Axiomatic
- ✓ State Machines
- ✓ Decision Tables
- ✓ Cause-effect

*We will not cover algebraic and axiomatic testing as they require math. background knowledge that is outside the scope of this course.*

The specification must be provided in certain format. Otherwise, these testing techniques cannot be used.

# Test Selection Problem

## Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

- The input domain of a program consists of all possible inputs that could be taken by the program.
- Ideally, the test selection problem is to select a **subset T** of the input domain such that the execution of T will reveal all errors.
- In practice, the test selection problem is to select a subset of T within budget such that it reveals as many errors as possible.

# Input Domain Testing

## Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

## Exhaustive or combinatorial testing (组合测试):

- Test every possible data value, valid and invalid, in every **possible combination**.
- Good for data-driven application: order-processing, form-based, transaction-based applications.

### Problems

- ⊗ Impossible to test all combinations
- ⊗ May overlook rare combinations, miss obscure paths
- ⊗ Generally covers only the 'expected' inputs

# Too Many Combinations

## • Combinations of configuration parameter values

For example, telecoms software may be configured to work with different types of call (local, long distance, inter), billing (caller, phone card, 800), access (ISDN, VOIP, PBX), and server for billing (Win Server, Linux/MySQL, Oracle).

## • Combinations of input data values

For example, a word processing application may allow the user to select 10 ways to modify some highlighted text: subscript, superscript, underline, bold, italic, strikethrough, emboss, shadow, small caps, or all caps. With 10 binary inputs, 1,024 combinations ( $2^{10}$ ).

## • Combinations of test sequences

- ➔ For example, in mobile application, there are many steps and each step has many choices.
- ⊗ If there are k choices in each step, after n steps there are  $k \times k \times \dots \times k = k^n$  different test sequences.
- ⊗ It is not practical to test all these sequences!!

# Combinatorial Example: Find window

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

The Find window takes 3 inputs:

- **Find what** : a text string
- **Match case**: yes or no
- **Direction**: up or down

*We simplify this by considering only 3 values for the text string, say "Lee", "Yip" and "Chan".*

Page 21

Specification-based test – Part I

# Combinatorial Example

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

1. How many combinations of these 3 variables are possible?

- **Find what** has 3 values (Lee, Yip, Chan) (L Y C)
- **Match case** has 2 values (Yes / No) (Y N)
- **Direction** has 2 values (Up / Down) (U D)

2. List ALL the combinations of these 3 variables (total 12 cases)

LYU	YYU	CYU
LYD	YYD	CYD
LNU	YNU	CNU
LND	YND	CND

2	Yip	no	down	find Yip
3	abc	yes	up	'invalid input'

Page 23

Specification-based test – Part I

# Another Example: Ordering Pizza

Step 1 Select your favorite size and pizza crust.

Large Original Crust

Step 2

Select your favorite pizza toppings from the pull down. Whole toppings cover the entire pizza. First 1/2 and second 1/2 toppings cover half the pizza. For a regular cheese pizza, do not add toppings.

☒ I want to add or remove toppings on this pizza -- add on whole or half pizza.

Add toppings whole pizza

Add toppings 1st half

Add toppings 2nd half

$6 \times 2^{17} \times 2^{17} \times 2^{17} \times 4 \times 3 \times 2 \times 2 \times 5 \times 2$   
= WAY TOO MUCH TO TEST

Simplified pizza ordering:

$6 \times 4 \times 4 \times 4 \times 4 \times 3 \times 2 \times 2 \times 5 \times 2$   
= 184,320 possibilities

Step 3 Select your pizza instructions.

☒ I want to add special instructions for this pizza -- light, extra or no sauce; light or no cheese; well done bake

Regular Sauce Normal Cheese Normal Bake Normal Cut

Step 4 Add to order.

Quantity 1

Add To Order Add To Order & Checkout

Still too many cases to test!

Ref: From slides of Rick Kuhn and Raghu Kacker, Combinatorial Testing

# Reducing the test cases

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

Simplified pizza ordering:

$6 \times 4 \times 4 \times 4 \times 4 \times 3 \times 2 \times 2 \times 5 \times 2$   
= 184,320 possibilities

2-way tests: 32  
3-way tests: 150  
4-way tests: 570  
5-way tests: 2,413  
6-way tests: 8,330

If all failures involve 5 or fewer parameters, then we can have confidence after running all 5-way tests.

# How to minimize the number of test cases?

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

Try to sample from the input space in way that assures a certain level of combination coverage.

1. Test the most common or important combination, and then vary one or more parameters for the next test.

**All singles:** all individual valid values tested

For the **Find window** example, use 3 test cases:

(L, Y, U)

(M, N, D)

(C, Y, U)

2. Test all pair-wise combinations (given any 2 parameters, every combination of values of these two parameters are covered in at least one test case)

**All pairs (2-way)** → all pairs of valid values

For the ordering Pizza example: All pairs ⇒ 32 test cases

# How to minimize the number of test cases?

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

3. **All triples (3-way)** → all triplets of valid values

For the ordering Pizza example,  
All 3-way ⇒ 150 test cases

4. **All N-tuples** → all combinations of valid values

(N is the number of input parameters.)

Every possible combination of values of the parameters must be covered

Too many, *Not practical!*

For the ordering Pizza example,

All N-tuples ⇒  $6 \times 2^{17} \times 2^{17} \times 4 \times 3 \times 2 \times 2 \times 5 \times 2$  test cases!

# Example 2-way Interaction Fault in code

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

The fault occurs when: **pressure < 10 & volume > 300** (2-way interaction)

This fault is also called **double-mode fault**.

```
if (pressure < 10) {  
    // do something  
  
    if (volume > 300) {faulty code! BOOM!}  
    else { good code, no problem}  
}  
  
else {  
    // do something else  
}
```

## Error detection rates for interaction of 1 to 6

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

Results showed that across a variety of domains, all failures could be triggered by a maximum of 6-way interactions

Figure 2. Cumulative error detection rate for fault-triggering conditions. Many faults were caused by a single parameter value, a smaller proportion resulted from an interaction between two parameter values, and progressively fewer were triggered by three-, four-, five, and six-way interactions.

## Orthogonal Array (正交表) Testing

(Test all-pairs combinations, i.e. 2-way interactions)

Introduction

Spec-independent  
Input-based  
Input domain  
OA

EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

- Pairwise testing** method finds **double-mode faults**: 2 parameters conflicting with each other.

Example of double-mode fault: *one parameter overshadowing another, inhibiting required processing of that other parameter*

- when input is control-C, the return key will not work.
- When the font is Times and the menus are on the right, the tables don't line up properly.

- Most defects **are not** a result of complex interactions such as, "When the background is blue and the font is Times and the images are large and ... then the tables don't line up properly."

Page 30

Specification-based test – Part I

## Terminology

**Orthogonal Array.** Two-dimensional arrays that possess the interesting quality that by choosing any 2 columns in the array we receive an **even distribution** of all the pair-wise combinations of values in the array.

**OAs.** Written as  $OA(N, k^s, t)$ , or  $OA(N, k^s)$  if its strength is two. OA with N runs, k parameters, s levels, and strength t.

**Runs.** number of rows that are the potential test cases.

**Parameters.** number of columns that are parameters of interest.

**Levels.** The number of options or values for each parameter.

**Strength.** The number of columns it takes to see each option equally often. (For pairwise combination, the strength is 2)

- The number of runs (or test cases) is dependent on the number of parameters, levels, and strength.
- Example,  $OA(9, 4^3)$  means we have 9 runs (**test cases**) required to cover 4 parameters with 3 options each (see example on next page).
- Since the strength is assumed 2, this OA covers all pairs of parameters.
- $OA(64, 6^4, 3)$  means we have 64 runs required to cover all three-way combinations (strength 3) of six test parameters with four options each.

$OA(9, 4^3)$  ← Each parameter has 3 values

← Number of input parameters

Introduction

Spec-independent  
Input-based  
Input domain  
OA

EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

	A	B	C	D
1	0	0	0	0
2	0	1	1	2
3	0	2	2	1
4	1	0	1	1
5	1	1	2	0
6	1	2	0	2
7	2	0	2	2
8	2	1	0	1
9	2	2	1	0

← 4 parameters: (A, B, C, D)

9 test cases

Each parameter has 3 options (possible values), represented by 0, 1, 2.

The above OA covers every pair of A-B, every pair of A-C, every pair of A-D, every pair of B-C, every pair of B-D, and every pair of C-D.

# Orthogonal Array Testing Strategy (OATS)

Introduction

Spec-independent  
Input-based  
Input domain  
OA

EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

Steps:

1. Decide the number of parameters to test.
2. Decide which options to test for each parameter (how many values).
3. Find a suitable OA with the smallest number of runs to cover all parameters and options.  
(<http://www.research.att.com/~njas/oadir/>)
4. Map the parameters and options onto the array.
5. A given test situation may not need all the parameters or all the options that a particular OA provides.  
Choose values for any options that are not needed (call them **leftovers**) from the valid remaining options and delete any columns that are not needed.
6. Transcribe the runs into test cases, adding additional combinations as needed.

Specification-based test – Part I

# Summary

Introduction

Spec-independent  
Input-based  
Input domain  
OA

EP

BV

CT

Worst case

Function-based

Spec-dependent

Other

- Empirical research suggests that all software failures caused by interaction of few parameters (between 2 to 6)
- OA is useful for
  - ✓ integration testing of software components,
  - ✓ web e-commerce systems,
  - ✓ communication protocols, and
  - ✓ configuration testing

- Not useful
  - Small number of parameters, where exhaustive testing is possible
  - No interaction between parameters, so interaction testing is pointless.

Testing tool:

- From NIST called ACTS, <http://csrc.nist.gov/acts>
- <http://www.pairwise.org/>

43

Specification-based test – Part I

# Equivalence Partitioning (EP) Testing

All Inputs are not alike!!

Adapted from Ian Sommerville "Software Engineering"

Page 44

Specification-based test – Part I

# Example: Square Root Specification

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

To calculate the square root of a real number:

Input: real number

Output: real number

- (1) For an input of 0 or greater, the positive square root of the input shall be returned.
- (2) For an input of less than 0, a value of 0 will be returned and output 'illegal input'.

Values  $< 0$  will be rejected,  $\geq 0$  will be accepted and process.

There are 2 input classes:

all possible values  
that are  $< 0$

all those that  
are  $\geq 0$

From the point of view of the requirements, all values within such a class are **equivalent** (but not equal).

Page 45

Specification-based test – Part I

# Equivalence Partitioning Testing (1)

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

**Partition:** a collection of mutually disjoint subsets whose union is the entire set.  
(A set of **equivalent classes**)

Why important?

1. disjointedness assures a form of **non-redundancy**
2. the entire set implies a form of **completeness**

⌘ Elements in the same equivalent class have something in common.

Identify test cases by using one element from each equivalence class.

Page 46

Specification-based test – Part I

# Equivalence Partitioning Testing (2)

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

- ⌘ Identify interesting classes of input, where each class is representative of many possible tests.
- ⌘ Two tests belong to the same equivalence class if we expect the **same result (pass/fail)** of each. Testing multiple members of the same equivalence class is redundant and waste time!
- ⌘ EP testing is appropriate
  - ✓ when input data is defined in terms of ranges and sets of discrete values (ordered set).
  - ✓ when the program function is complex. The complexity of the function can help identify useful equivalence classes

Page 47

Specification-based test – Part I

# What is *Equivalence*?

- **Intuitive Similarity:** two test values are equivalent if they are so similar to each other that it seems pointless to test both.
- **Specified As Equivalent:** two test values are equivalent if the specification says that the system handles them in the same way.
- **Equivalent Paths:** two test values are equivalent if they would drive the program down the same path  
**But**, 2 values might take the program down the same path but have very different effects (e.g. word processor's output may be the same but may yield different results from different printers.)

Page 48

Specification-based test – Part I

# Example Equivalence partitioning

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

A program accepts 4 to 10 five-digit integer inputs (e.g., 14617, 92210, 25999, 45411)

- Partition system inputs into 'equivalence sets'  
The equivalence partitions for five-digit integer are:
  - > < 10,000 (invalid integer)
  - > 10,000-99,999 (valid integer)
  - > > 99,999 (invalid integer)
- Then, we choose one input from each partition:
  - 05000, 59999, 120001

## Another partition:

- Input with 4 to 10 5-digit integers: (12340, 98980, 23456, 49821, 98765, 22222)
- Input with <4 5-digit integers: (12340, 98980, 23456)
- Input with >10 5-digit integers: (12340, 98980, 23456, 49821, 98765, 22222, 34341, 56565, 77777, 59090, 67890)

## Equivalence Partitioning Testing (3)

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

⌘ Running one test from each *equivalence class* will avoid wasting time repeating what is virtually the same test.

## 2 steps of applying EP testing:

- (1) Identify equivalence classes (EC)
- (2) Identify test cases

Page 51

Specification-based test – Part I

## 1. Identifying Equivalence Classes (1)

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

→ if the external input specifies a range of valid values, define 1 valid EC within the range, and 2 invalid EC (outside each end of the range)

E.g. the sale item count can be from 1 to 999

EC: [1-999], [<1], [>999]

TC 1: sale item count = 21

TC 2: sale item count = 0 (invalid)

TC 3: sale item count = 1001 (invalid)

→ if the external input specifies the number (N) of valid values, define 1 valid EC and 2 invalid ECs (less than N, and more than N)

E.g. if the input requires 4 book titles

EC: [4], [<4], [>4]

TC 1: 4 book titles (valid)

TC 2: 2 book titles (invalid)

TC 3: 10 book titles (invalid)

Page 52

Specification-based test – Part I

# 1. Identifying Equivalence Classes (2)

→ if the external input must belong to a group, define 1 valid EC within the set and 1 invalid EC outside the set

e.g.1 Type of vehicle must be {Bus, Taxi, Truck, Cycle}

EC: [Bus, Taxi, Truck, Cycle], [any other values]

TC 1: Taxi (randomly pick a value from the set)

TC 2: Trailer (invalid)

e.g. 2 Enter the name of a country

TC 1: any country name - China

TC 2: input that is not a country name -Earth

→ if the external input specifies a list of possible inputs and the program responds differently to each, each input in the list is its own equivalence class. The invalid equivalence class includes any inputs not on the list.

e.g. Program asks "Are you sure? (Y/N)"

EC: [Y], [N], [any other values]

TC 1: Y

TC 2: N

TC 3: X

# 1. Identifying Equivalence Classes (3)

→ If the external input specifies a 'must be' situation, define one valid EC and one invalid EC.

e.g., The first character of a field must be alpha

EC: [all strings with the first character alpha], [all other strings not start with alpha]

TC 1: hare234

TC 2: 123hare

→ if the external input items must calculate to a certain value or range, define one valid EC that satisfy the required value or range, and one invalid EC that does not.

e.g., Enter the three angles of a *triangle*

EC: [all 3 values which add to 180], [any 3 values not add to 180]

TC 1: (20, 60, 100)

TC 2: (100, 100, 20) (invalid)

→ For each external input, if there is reason to believe that elements in an EC are not handled in an identical manner by the program, subdivide the EC into smaller ECs.

→ This depends on the experience and skill of the tester

⌘ If we know that the system may react in different ways to invalid input, we must build several invalid ECs

## 2. Identifying Test Cases

Introduction

Spec-independent  
Input-based

Input domain

EP

BV

CT

Worst case

Function-based

Spec-dependent

Other

⌘ Until all **valid** ECs have been covered by test cases, write a new test case covering as many of the uncovered ECs as possible.

⌘ Until all **invalid** ECs have been covered by test cases, write a test case that covers one, and only one, of the uncovered invalid ECs.

If multiple invalid ECs are tested in the same test case, some of those tests may never be executed because the first test may mask other tests or terminate execution of the test case.

Use more test cases rather than one test case to test many invalid ECs.

## Summary of Applying EP (1)

Introduction

Spec-independent  
Input-based

Input domain

EP

BV

CT

Worst case

Function-based

Spec-dependent

Other

1. For each requirement, determine the inputs to the requirement.

- Inputs are anything that influences the functionality or the behavior of the requirement, and any kind of data that is needed in order to process the requirement.

Example: **"if a file is to be deleted, the system prompts the user with a confirmation request, where the user can confirm or cancel deletion."**

Answers to this request: "confirm" or "cancel". The answer either causes the file to be deleted or keeps the file. It influences the behavior, so it is an input.

2. If the requirement does not contain all the information necessary to identify its inputs, identify where other relevant information is located (other documents, etc).

- For each input, divide the input domain into EC.

## Summary of Applying EP (2)

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

3. When it is not possible to create ECs just by looking at one input, because the effect of one input depends on the effect of another input. The requirement is too complex because it contains several requirements.

Break the requirement down into several smaller ones:

- If the requirement consists of several steps. Write down each of these steps.
- Write a separate requirement for each of these steps, using the information from the original requirement.

Example requirement: **The user can choose to delete a file and is then asked to confirm that they really want to delete it.**

*How many inputs?*

## Summary of Applying EP (3)

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

Two inputs:

- The user's decision to delete a file
- The user's confirmation of that action.

The behavior depends on the combination of both inputs.

We can identify two steps, corresponding to the inputs:

- the user can choose to delete a file, and
- the user has to confirm deletion.

We thus write a requirement for each of these steps:

- The user can choose to delete a file
- if a file is to be deleted, the system prompts a confirmation request, where the user can confirm or cancel deletion.

## EC Example: A Banking Application

Introduction

2	604	1345	1234	hello	abc

We combine several ECs together to form a test case.

How to combine these different ECs?

There are 2 ways: **WEC** and **SEC**

Page 62

Specification-based test – Part I

## 2 Types of EC Testing

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

### (1) Weak Equivalence Class (WEC) Testing

- ⌘ Use one variable from each EC in a test case
- ⌘ We will always have the same number of weak EC test cases as there are classes in the partition with the largest number of subsets.

### (2) Strong Equivalence Class (SEC) Testing

- ⌘ Based on the Cartesian Product of the partition.
- ⌘ Achieve 'completeness': we cover all the EC, and we have one of each possible combination of inputs.
- ⌘ Strong EC testing assumes that the variables are independent when the Cartesian Product is taken. If there are any dependencies, these will generate impossible test cases
- ⌘ SEC is more **thorough** than WEC.

Page 63

Specification-based test – Part I

## Example WEC and SEC

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

Assume that the airfare depends on the age of the passenger, high or low season, and time of the day.  
The input consists of 3 values: (*age, date, time*)

### Input equivalent partitions:

Age: [1 to 4], [5 to 18], [19 to 60]  
[>60] --- (4 partitions)  
Date: [April to September],  
[Oct. to March],  
[Christmas period],  
[Easter holiday] --- (4 parti)  
Time: [10 am to 8pm],  
[8pm to 10am] --- (2 parti)

### Test cases using WEC:

[2, May, 11am]  
[6, Oct, 10pm]  
[21, Christmas, noon]  
[65, Easter, 2am]  
Every partition has been tested at least once.

Total test case for WEC: 4

### Total test case for SEC:

$4 \times 4 \times 2 = 32$

How to reduce this?

Page 64

Based on spec

# Boundary Value Testing

(Counterpart of Domain Testing, which is based on source code)

## Boundary Value Testing (1)

- Many errors tend to occur at the **boundaries** of the input domain (e.g., off-by-one defects, forget to handle empty set).
- BV testing complements equivalence partitioning. Rather than select any element in an equivalence class, we select those at the "edge" of the class.
- We aim to detect "boundary" errors.

### Example:

A method M is supposed to compute a function f1 when condition  $x \leq 0$  and function f2 otherwise. However, M has an error such that it computes f1 for  $x < 0$  and f2 otherwise.

## BV Example

A program simulates water in a chemical plant. Water freezes at 0C and boils at 100C.

=> Meaningful partitions are: ( $<0$ ), ( $0-100$ ), and ( $>100$ ).

If we use EP testing, we will have 3 test cases: one value from each of the three partitions. The reason being that if the program works at 12C, it should also work at 55C.

If we use BV testing, select the following test cases:

-1C, 0C, 1C,  
99C, 100C, 101C

## Boundary Value Testing (2)

- Boundary conditions may be subtle and difficult to identify.
- BV also incorporates *negative testing*, as it recommends test cases outside the boundary.

Example: months 0 and 13 are good boundary cases.

### Steps:

- Partition the input domain
- Identify the boundaries for each partition
- Select test data such that each boundary value occurs in at least one test input

# Identifying BV Test Cases

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

1. If an input condition specifies a range bounded by values a and b, select the following tests:
  - a, values just above a, values just below a
  - b, values just above b, values just below bThat is, we use values (a-1), a, (a+1), (b-1), b, (b+1).
2. If an input condition specifies a number of values, select tests that exercise the min. and max. numbers. Also, values just above and below min. and max. (That is, (n-1), n, and (n+1)). *See the example on previous page.*

Page 69

Specification-based test – Part I

# Boundary Value Testing (3)

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
Worst case

Function-based

Spec-dependent

Other

## Advantages:

- expose any errors that affect an entire equivalence class.
- expose errors that mis-specify a boundary.
  - coding errors (off-by-one errors) or typing mistakes (such as entering 57 instead of 75 that defines the boundary).
  - Mis-specification result from ambiguity or confusion about the decision rule that defines the boundary.

## Disadvantages:

- ⊗ Would not work for Boolean variables and logical variables
- ⊗ Do not test dependencies among the variables
- ⊗ Do not consider combinations of input/output conditions!

Page 70

Specification-based test – Part I

# BV Example: Business Rule

Introduction

Spec-independent  
Input-based

Specification-based test – Part I

## EP summary

#tests: small to moderate  
Usage: some study of requirements needed

When to use:

- independent inputs
- ordered sets
- when suspecting computational errors
- may easily be combined with BV testing

## BV testing summary

#tests: moderate to very many

Usage: straightforward, easy to implement

When to use:

- independent inputs
- ordered sets
- when suspecting boundary errors (such as miscoding of boundaries or ambiguity in definition of the valid/invalid sets.)

Specification-based test – Part I

# Comparing EP and BV Testing

- BV testing has no recognition of data or logical dependencies. They are easy to automate.
- EP testing pays attention to data dependencies and to the function itself. Thus, more thought is required to identify the EC.
- In an ordered set, **boundaries** mark the point or zone of transition from one EC to another.

Assume that domain can be partitioned into 4 EC shown right.

**X** are the test cases for EP testing

\* are the test cases for BV testing

Specification-based test – Part I

# Classification-tree Method

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
**CT**  
Worst case

Function-based

Spec-dependent

Other

- ⌘ Aims to identify all the feasible combinations of classes as test cases
- ⌘ Enables systematic test case design– minimize the chance of overlooking some important test cases.
- ⌘ Can apply to informal and formal specification.
- ⌘ Easy to understand from the graphical representation

The size of the classification tree can be a measure of a system's complexity. The number of test cases from the CTM can help to estimate the testing effort and development effort.

Tool available (Classification-Tree Editor CTE XL):  
[www.systematic-testing.com](http://www.systematic-testing.com)

Specification-based test – Part I

# Classification-tree Method

**Classifications** are the input parameters and environment condition of the module that will affect its execution behavior. Can look at the interface description (or input to the system)

Classifications are different criteria for partitioning the input domain of the problem to be tested.

**p-type:** based on explicit input parameter to the system

*Example: input of invoice amount ( $> 0$ ,  $=0$ ,  $<0$ ),  
input of approval (yes or no)*

**e-type:** do not depend on the input; based on environmental condition

*Example: the status of Customer Master File (does not exist, exist).*

**Classes** are the non-overlapping subsets of the values of the corresponding category. Given by values or intervals.

Testers will manually create classes for each classification, based on the requirement specification or functional specification.

# Classification-tree Method

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
**CT**  
Worst case

Function-based

Spec-dependent

Other

- Decompose the specification into modules that can be tested independently.
- For each module selected for testing, repeat the following steps:
  - Identify a set of classifications and classes for the module.
  - Construct a classification tree from the identified classifications and classes
  - Construct a test case table from the classification tree
  - Construct test cases:
    - ⌘ Identify all the feasible combinations of classes from the test case table. Each combination of classes represents a test case.
    - ⌘ For each test case, identify concrete test values to serve as test data.

## Example: TRADE System

A goods trading system, TRADE, shall be developed for the HK Wholesale. For each credit purchase, the system accepts the customer and purchase details to determine whether this purchase should be approved.

### Function of TRADE:

1. Accept the customer number.
2. Check the customer number against the Customer Master File. If the customer number exists, go to step 3. Otherwise, reject the transaction and stop.
3. Check the status of the customer. If it is deactivated, go to step 4. Otherwise, go to step 5.
4. Check whether the transaction is supported by special management approval. If yes. Accept the transaction and stop. Otherwise, reject the transaction and stop.
5. Compare the credit limit and the invoice amount. If the credit limit is less than the invoice amount, reject the transaction. Otherwise, accept the transaction.

Details of customer number, invoice amount, and management approval are manually entered by users.

Other details, such as customer's status and credit limit, are automatically retrieved from the Customer Master File by TRADE.

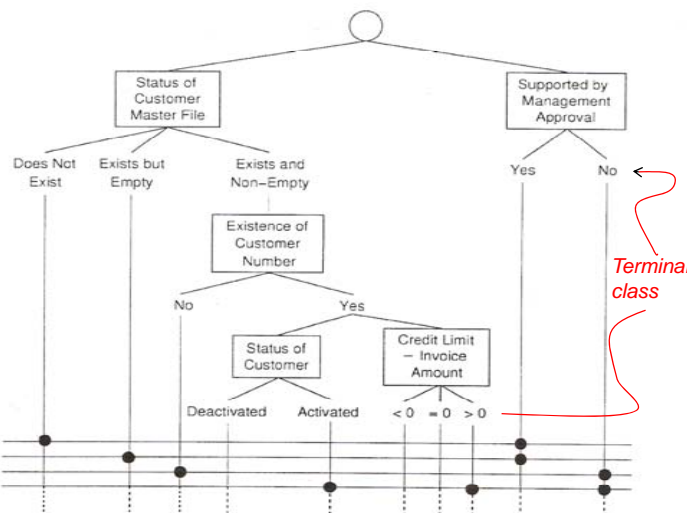

## Classification and Classes of TRADE

	Classifications	Associated Classes
e-type	Status of Customer Master File	Does not exist, Exists but empty, Exists and non-empty
p-type	Existence of Customer Number	Yes, No
	Status of Customer	Deactivated, Activated
	Credit Limit – Invoice Amount	< 0, = 0, > 0
	Supported by Management Approval	Yes, No

## Part of Classification-tree for TRADE

The top node (root node) represents the whole input domain.

**Classifications** are enclosed in boxes; **classes** are not.

Test case table

## Drawing the Classification-tree

### Introduction

### Spec-independent Input-based

### Input domain

### EP

### BV

### CT

### Worst case

### Function-based

### Spec-dependent

### Other

From CT, test cases can be expressed in the test-case table:

1. Draw the grids of the test-case table under CT. The columns of the table correspond to the terminal nodes of CT. The rows correspond to test cases.
2. Construct a test case in the test-case table by selecting a combination of classes in CT as follows:
  - a) Select one and only one child class of each top-level classification
  - b) For every child classification of each selected class, recursively select one and only one child class.

# How many test cases?

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
**CT**  
Worst case

Function-based

Spec-dependent

Other

- ⌘ **Minimum** criterion: each terminal class is include at least once in a test case. (our example: 3)
- ⌘ **Maximum** criterion: all permitted combinations of terminal classes are included. (our example:  $3 \times 2 \times 2 \times 3 \times 2 = 72$ )  
Note: some combinations may not be possible!! So the feasible combination is normally less than the maximum number.
- ⌘ **Good rule**: total number of terminal classes gives sufficient test coverage – test all values of terminal classes (our example:  $3 + 2 + 2 + 3 + 2 = 12$ )

Page 85

Specification-based test – Part I

# Observations

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
**CT**  
Worst case

Function-based

Spec-dependent

Other

- ⌘ More than one correct classification tree may be constructed – depend on the tester  
Which one is better?  
Look at number of classification and classes, ease of understanding, effectiveness in generating valid test cases.
- ⌘ How to apply CTM to complex specification?  
Decompose it into smaller modules that can be independently tested.
- ⌘ Incorrect classification are caused by a partial understanding of the problem domain of the specification.
- ⌘ **Common problems**: overlapping classes, not enough decomposition (divide a class into sub-classes)

Page 86

Specification-based test – Part I

# Guideline of Using CTM

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
**CT**  
Worst case

Function-based

Spec-dependent

Other

- ⌘ For defining classification, think about p-type & e-type.
- ⌘ For defining classes, think about the “boundary cases.”
- ⌘ Should not construct the CT based on “control-flow” – CT is based is data-oriented, black-box testing.
- ⌘ Avoid using control-flow information unconsciously for constructing the classification.
- ⌘ There may be some logical dependencies between classes. Keep this in mind when preparing the test cases.
- ⌘ Combination Rule: Some classifications and classes may be more important than others. Example: **size** and **form** are more relevant to testing than **color** in a computer vision system. Try to include all possible combinations of **size** and **form**

Classification Tree provides a visual representation of system requirements.

Page 87

Specification-based test – Part I

# Worst Case Testing

Introduction

Spec-independent  
Input-based

Input domain  
EP  
BV  
CT  
**Worst case**

Function-based

Spec-dependent

Other

- ⌘ Try to test when more than one variable has an extreme value.
- ⌘ More thorough than boundary value testing
- ⌘ But this requires more effort, as all combinations are tested.
- ⌘ Similar to the **strong equivalence class** testing in terms of selecting many test cases

Example: test the accounting package with the largest amount and a user name with the longest string.

Page 88

Specification-based test – Part I

# Functional Testing

Introduction

Spec-independent  
Input-based

Function-based

Spec-dependent

Other

A function is something the system can do (also called features / commands)

- ⌘ Function testing is usually the first black box test to use.

*"Test what it can do"*

**Fundamental goal:** Test each function thoroughly, one at a time.

- ⌘ Demonstrate each required function
- ⌘ No reference is made to the implementation (i.e., the source code)

# Some Function Testing Tasks

Introduction

Spec-independent  
Input-based

Function-based

Spec-dependent

Other

- (1) Identify each function and sub-function
  - From specifications or the draft user manual, design, externally observable behavior, walking through user interface, searching the program for command names
- (2) From this information, build the function list

**Example: For each category of function (e.g. Editing)**

- **For Individual functions (e.g. Cut, Paste, Delete), identify**
  - Inputs to the function (Variable: try Maximum, Min, special cases)
  - Outputs of the function
  - Possible scope of the function (e.g. Delete word, Delete paragraph)
  - Options of the function (e.g. configure the program to Delete the contents of a row of a table, leaving a blank row)
  - Circumstances under which the function behaves differently (e.g. deleting from a word processor configured to track and display changes or not to track changes)

# Some Function Testing Tasks

Introduction

Spec-independent  
Input-based

Function-based

Spec-dependent

Other

- (3) When building or using the function list:

- Determine how we would know if the function worked.
- Identify variables used by the functions and test their boundaries.
- Identify environmental variables that may constrain the function under test.
- Check that each function does what it's supposed to do (**positive test**) and does not do what it's not supposed to do (**negative test**).

# Function Testing Example

Introduction

Spec-independent  
Input-based

Function-based

Spec-dependent

Other

How to ensure we adequately test the function?

Step 1: physically partition the functional specification into separate requirements (note: the requirements may not be independent)

Step 2: create test cases for each partitioned requirement.

**Example:**

*"Given as input two integers x and y, output all the numbers smaller than or equal to x that are evenly divisible by y. If either x or y is zero, then output zero."*

## Function Testing Example: Requirements Partitioning

Introduction

Spec-independent  
Input-based

Function-based

Spec-dependent

Other

*"Given as input two integers x and y"*

R1: accept 2 integers as input.

*"output all the numbers"*

R2: output zero or more (integer) numbers.

*"smaller than or equal to x"*

R3: All numbers output must be less than or equal to the first input number.

*"evenly divisible by y"*

R4: All numbers output must be evenly divisible by the second number.

*"all the number"*

R5: output must contain all numbers that meet both R3 and R4.

*"If either x or y is zero, then output zero."*

R6: output must be zero (only) in the case where either first or second input integer is zero.

## Function Testing Example: Test case selection

Introduction

Spec-independent  
Input-based

Function-based

Spec-dependent

Other

We model each partitioned requirement as independent.

We create separate test cases for each partitioned requirement.

For our example, we choose test cases for R6:

R6 Test1: 0 0 (both zero)

R6 Test2: 0 1 (x zero, y not)

R6 Test3: 1 0 (y zero, x not)

R6 Test4: 1 1 (neither zero)

*and other test cases. . .*

## Primary Uses of Function Testing

Introduction

Spec-independent  
Input-based

Function-based

Spec-dependent

Other

- **Check coverage**
  - we check our test plan or set of test cases against the function list, for coverage of every feature, and every option and subfunction of every feature.
- Useful for **initial testing** of the product
  - Learn the capabilities of the product
  - Fast scan for serious problems that should be addressed early
- Best for assessing **capability** rather than reliability

## Risks of Function Testing

Introduction

Spec-independent  
Input-based

Function-based

Spec-dependent

Other

- **Problems** with using this testing method only :
  - Significant redundancies among test cases (may test the same program path over and over again).
  - Not able to test behavior not specified
  - Misses feature interactions
  - Misses load-related issues, interaction with background tasks, effects of interrupts
  - Often focuses on the features without considering boundaries or other tests of special data
  - Doesn't address user tasks—whether the customer can actually achieve the benefits promised by the program

# Special-value Testing

Introduction

Spec-independent  
Input-based

Function-based

Special-value  
Output range

Spec-dependent

Other

- ⌘ Tester uses his domain knowledge, experience with similar programs, etc to devise test cases
- ⌘ Very dependent on the ability of the tester.
- ⌘ Highly subjective. But, it often results in a set of test cases which is more effective in revealing faults than other methods.
- ⌘ Select test data on the basis of features of the function to be computed.
- ⌘ Properties of the function to be computed can aid in selecting input which will indicate the accuracy of the computed solution.  
e.g., Feb. 29 for Y2K problem

Page 97

Specification-based test – Part I

# Examples of Special-value

Introduction

Spec-independent  
Input-based

Function-based

Special-value  
Output range

Spec-dependent

Other

**Zeroes or nulls:** these have the property that they do not generate a change in value for addition or subtraction.

**Ones:** these do not generate changes in values for multiplication and division.

- ⌘ Always include these values in our test!

Example: a function that sorts a collection of numbers.

- ⌘ We should test using
  - (1) the empty set
  - (2) a set of one item.

Page 98

Specification-based test – Part I

# Output Range Coverage

Introduction

Spec-independent  
Input-based

Function-based

Special-value  
Output range

Spec-dependent

Other

- ⌘ Each function has an associated output range.
- ⌘ Select test cases that will cause the **extremes** of each of the output ranges to be achieved.
- ⌘ Check for (1) maximum and minimum output conditions and (2) that all categories of error messages have been tested.
- ⌘ In general, constructing such test data requires knowledge of the function to be computed and, hence, expertise in the application area.
- Must analyse requirements to figure out what input is required to produce each output - this can be a complex and time consuming analysis.

Page 99

Specification-based test – Part I

# Output Range Coverage

Introduction

Spec-independent  
Input-based

Function-based

Special-value  
Output range

Spec-dependent

Other

- This technique can be very effective in finding problems, because it requires a deep understanding of the requirements

- ⌘ But, this technique is difficult to use.

## Example

A program that will print the class list.

Each class can have at most 60 students and no fewer than 10 students.

Test cases:

- ⌘ Try to print a class of 60 students
- ⌘ Try to print the class with 10 students.

Output boundary

Page 100

Specification-based test – Part I

# Exhaustive Output Testing

Introduction

Spec-independent  
Input-based

Function-based

Special-value  
Output range

Spec-dependent

Other

Have one test for every possible output.

**Practical more often than exhaustive input testing**, because programs are often written to reduce or summarize input data.

But still impractical in general – most programs have an infinite number of different possible outputs.

**Example:** The requirements say:

*"output 1 if two input integers are equal, 0 otherwise."* [only 2 possible output!!]

2 integer inputs – doing input partitioning, we have many test cases:

- Numbers equal
- Numbers not equal
- First number zero/ positive/ negative
- Second number zero/ positive/ negative.

But, we can do exhaustive output testing with only 2 test cases : output 1, output 0.

# Output Partition Testing

Introduction

Spec-independent  
Input-based

Function-based

Special-value  
Output range

Spec-dependent

Other

Output range

- ⌘ **Output partitioning** is like input partitioning, only we analyse the possible outputs.
- ⌘ Similar to input partitioning, we partition all the possible outputs into a set of equivalence classes which have something in common.
- ⌘ Once we have the output partitions, we must design inputs to cause outputs in each class.
- ⌘ This is a **difficult and time consuming task**.
- ⌘ Sometimes, we discover that we cannot find such an input – *this implies an **error** or **oversight** in either the requirements or in the partition analysis.*

Page 102

Specification-based test – Part I

## Warnings & Errors

The man is smoking and leaving smoke rings into the air.

His girlfriend gets irritated with the smoke and says:

*"Can't you see the warning written on the cigarettes packet, smoking is injurious to health!"*

The man replies back:

*"I am a programmer.  
We don't worry about warnings,  
we only worry about errors."*

## Supplementary Notes

Page 103

Specification-based test – Part I

Page 104

Specification-based test – Part I

## Example 2 of OATS (pairwise testing) (1)

Given an object-oriented system that contains a client class (C1) with 2 subclasses (C2 and C3). These client classes interact with a server class hierarchy consisting of class S1 with subclasses S2 and S3. The server class contains a method `foo()` which takes an instance of class M1 as a parameter. M1 has 2 subclasses, M2 and M3.

## Example 2 (2)

To test all combinations of the classes involved, it would take 27 test cases (3 clients that can each send 3 messages to 3 servers --  $3 \times 3 \times 3 = 27$ ).

- That assumes that the method `foo()` can be tested with only a single test case.
- But, in most circumstances, it will take many test cases to test a particular method.

Thus, there are many more test cases in practices!

## Example 2 (3)

Using the OATS technique:

1. There are 3 independent variables (the client, the server, and the message class).
2. Each variable can take on 3 values.
3. Ideally, we would use an array that contains three levels and three parameters (an  $OA(?, 3^3)$ ).

However, no such published array exists. Therefore, we need to look for the smallest array that will handle our problem.

$OA(9, 4^3)$  will work. It has the three levels for the values and four parameters is more than enough for the three variables.

## Example 2 (4)

4. Mapping the values onto the array:

A. For Client, C1=0; C2=1; C3=2.

B. For Server, S1=0; S2=1; S3=2.

C. For Message, M1=0; M2=1; M3=2.

$OA(9, 4^3)$

	A	B	C	D
1	0	0	0	0
2	0	1	1	2
3	0	2	2	1
4	1	0	1	1
5	1	1	2	0
6	1	2	0	2
7	2	0	2	2
8	2	1	0	1
9	2	2	1	0

	Client	Server	Message
Test 1	C1	S1	M1
Test 2	C1	S2	M2
Test 3	C1	S3	M3
Test 4	C2	S1	M2
Test 5	C2	S2	M3
Test 6	C2	S3	M1
Test 7	C3	S1	M3
Test 8	C3	S2	M1
Test 9	C3	S3	M2

5. There are no "left over" Levels.

But, we notice that there was an extra parameter in  $OA(9, 4^3)$ . This parameter can simply be ignored. We still get an even distribution of the pair-wise combinations.

6. We end up with 9 test cases.

## Another Pairwise coverage Example

An application that is intended to run on a variety of platforms comprised of 5 components: an operating system (Windows XP, Apple OS X, Red Hat Linux), a browser (Internet Explorer, Firefox), protocol stack (IPv4, IPv6), a processor (Intel, AMD), and a database (MySQL, Sybase, Oracle),

There are  $3 \times 2 \times 2 \times 2 \times 2 = 48$  possible platforms.

With only 10 tests, it is possible to test every component interacting with every other component at least once, i.e., all possible pairs of platform components.

Test	OS	Browser	Protocol	CPU	DBMS
1	XP	IE	IPv4	Intel	MySQL
2	XP	Firefox	IPv6	AMD	Sybase
3	XP	IE	IPv6	Intel	Oracle
4	OS X	Firefox	IPv4	AMD	MySQL
5	OS X	IE	IPv4	Intel	Sybase
6	OS X	Firefox	IPv4	Intel	Oracle
7	RHL	IE	IPv6	AMD	MySQL
8	RHL	Firefox	IPv4	Intel	Sybase
9	RHL	Firefox	IPv4	AMD	Oracle
10	OS X	Firefox	IPv6	AMD	Oracle

## Another EC Example: Phone System

Consider a program which dials a phone given a valid telephone number.

Equivalent classes based on the phone number:

- C1: local call (8 digits)
- C2: long distance (001+3 digits + 7 digits)
- C3: spaces as separators
- C4: hyphens as separators
- C5: () around the area code
- C6: Police call (911)
- C7: Directory assistance (1083)
- C8: too long
- C9: too short
- C10: invalid characters

## Example 2 of CT

Computer vision system: determine the size of different objects passing the camera of the system on a conveyor belt.  
Inputs are various building blocks.

What classification (or aspects)?

Size, Color and Form of the building blocks.

Classification for size: small, large building blocks

Classification for color: red, green, blue

Classification for form: triangular, circle, rectangular

## Example 2 of CT

Identify test cases:

We can continue, and have subclass under Triangular class:  
Shape of Triangle
